Comment from the Stata technical group. Item response theory (IRT) is used to evaluate the relationship between a latent trait, such as mathematical ability, quality of life, or patient satisfaction, and the test questions or items intended to measure that trait.

Here $\hat{\theta}_j$ are functions of $\hat{\theta}$ and x_j (see Section 3) and $\hat{\Sigma}$ is the covariance matrix of $\hat{\theta}_j$, usually specified as diagonal. 2.2 Non-continuous responses 2.2.1 Latent response formulation When the responses are dichotomous or ordinal, the same model as above can be

In 1895 and 1897, Cantor published a two-part paper in *Mathematische Annalen* under Felix Klein's editorship; these were his last significant papers on set theory. The first paper begins by defining set, subset, etc., in ways that would be largely acceptable now. The cardinal and ordinal arithmetic are reviewed.

In statistics (classical test theory), Cronbach's (alpha) is the trivial name used for tau-equivalent reliability as a (lowerbound) estimate of the reliability of a psychometric test. Synonymous terms are: coefficient alpha, Guttman's τ , Hoyt method and KR-20. It has been proposed that can be viewed as the expected correlation of two tests that measure the same construct.

Box and Cox (1964) developed the transformation. Estimation of any Box-Cox parameters is by maximum likelihood. Box and Cox (1964) offered an example in which the data had the form of survival times but the underlying biological structure was of hazard rates, and the transformation identified this.
